Abstract—Video captioning refers to automatic generate natural language sentences, which summarize the video contents. Inspired by the visual attention mechanism of human beings, temporal attention mechanism has been widely used in video description to selectively focus on important frames. However, most existing methods based on temporal attention mechanism suffer from the problems of recognition error and detail missing, because temporal attention mechanism cannot further catch significant regions in frames. In order to address above problems, we propose the use of a novel spatial-temporal attention mechanism (STAT) within an encoder-decoder neural network for video captioning. The proposed STAT successfully takes into account both the spatial and temporal structures in a video, so it makes the decoder to automatically select the significant regions in the most relevant temporal segments for word prediction. We evaluate our STAT on two well-known benchmarks: **MSVD** and **MSR-VTT-10K**. Experimental results show that our proposed STAT achieves the state-of-the-art performance with several popular **evaluation metrics: BLEU-4, METEOR, and CIDEr**.

Index Terms—Video captioning, spatial-temporal attention mechanism, encoder-decoder neural networks.

I. INTRODUCTION

THE goal of video captioning is to make computer understand what is happening in a given video and establish the bridge between the video content and its meaningful natural language description [1]–[8]. It has been extensively used to many applications, for instance, it may help users of video sites to retrieve videos efficiently, or benefits visually impaired people for better understanding of the video content. However, since a video clip often involves complex interactions of actors and objects that evolve over time, it is still a challenging task to automatically generate an accurate description for the complicated sequence of events.

Video captioning has become an active and flourishing research topic in recent years, and the most effective method is the encoder-decoder neural networks, in which 2D or 3D convolutional neural networks (CNNs) are utilized for video content encoding and recurrent neural networks (RNNs) for decoding to a sentence. Early work with this method attempted to encode an entire video into a single feature vector, which is prone to clutter, because temporally distinct events and objects will be potentially fused incoherently. In order to address the problem, recently, some work incorporated temporal attention mechanism (TAT) [9]–[12] into the encoder-decoder network to exploit the temporal structure underlying the video. Rather than encode an entire video into a single feature vector, temporal attention mechanism can make the decoder selectively focus on a small subset of frames by attention weights. Therefore, each word is generated according to the most relevant frames.

Although temporal attention mechanism can select important frames for word prediction, it cannot further catch significant regions in these frames. When there is clutter in some frames, this drawback can result in the problems of detail missing and object misprediction. As shown in Fig. 1(a), the ‘bear’ is mispredicted as ‘panda’; as shown in Fig. 1(b), the ‘phone’ is missed. When we are asked to describe the main content of a video, we have a large possibility to only mention the semantic of the regions of significance in some frames. Hence, besides temporal structure in an entire video, exploiting spatial structure in each frame is also necessary for generating more accurate and detailed description.

To take full advantage of the spatial and temporal structure in a video, a novel spatial-temporal attention mechanism (STAT) is proposed in this work, which is our major contribution. Furthermore, global features and motion features, which are both at frame-level, are widely used in previous work. In this paper,

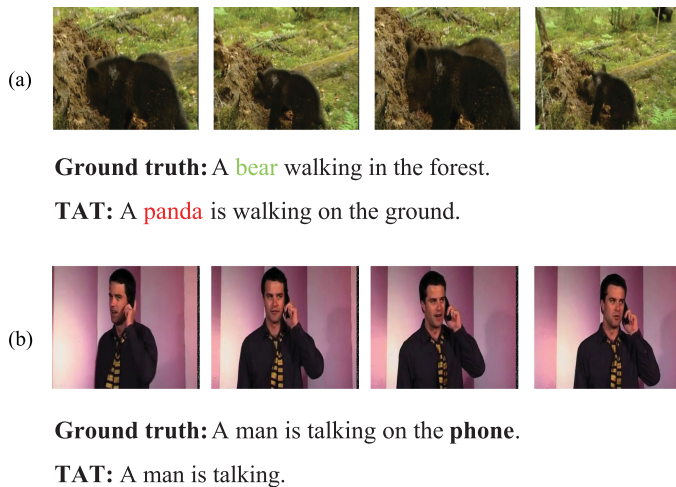

Fig. 1. Illustration of problems of the object misprediction ((a): misrecognizing ‘bear’ as ‘panda’) and detail missing ((b): missing ‘phone’), where TAT represents temporal attention mechanism.

in addition to global and motion features, we expand the feature set to include the local features at object-level, which can represent accurate semantic concepts of objects in each frame. While generating a description, the proposed STAT not only selectively focuses on important frames, but also further catches significant regions in those frames, making it possible for the decoder to obtain enough input information and conduct accurate decoding. Therefore, our proposed STAT can generate more relevant video description sentences.

The rest of this paper is organized as follows. Firstly, it reviews the existing materials in Section II. Then, it presents the overview of our framework and expounds on the details of STAT in Section III. After that, it gives the evaluation of STAT on different dataset and analyzes the performance in Section IV. Finally, it comes to the conclusion, together with the discussions for future work.

II. RELATED WORK

In this work, we provide relevant background on previous work on video captioning, temporal attention mechanism and exploitation of local features.

Video Captioning: Up to now, some methods have been proposed for addressing the problems of video captioning, and these approaches have proved to be significant progress. These methods could be roughly classified into three types, depending on the manner in which the sentences are generated. (1) template-based method; (2) the method based on neural network.

Template-based method [13]–[17] firstly predicts semantic concepts or words (e.g., subjects, objects and verbs) by different classification methods, then employs a pre-defined sentence template to form them into a description. This method is intuitive, but need to deal with the complex data. Meanwhile, the limitation of sentence template cannot flexibly generate meaningful sentences [5].

With the development of deep learning, recent work [5]–[8], [18], [19] turn to employ neural network-based method to

automatically generate video description. The approach is mainly based on the encoder-decoder framework which aims to translate video contents directly into sentences. More specifically, an encoder 2-D/3D-Convolutional neural network (CNN) converts input into a vector representation of a fixed length, which is then fed into a decoder LSTM to generate natural sentences. For instance, Venugopalan *et al.* [20] has applied neural network-based method to automatically generate video description. They tried to represent the information using a single, temporarily folded feature vector. However, they failed to exploit temporal structure in a video. This may lead to generate wrong sentences, because different events and objects in temporal sequence may fuse incoherently [11]. In order to solve the problem, Pan *et al.* [10] tried to exploit a hierarchical recurrent encoder to model video temporal information. Yao *et al.* [11] attempted to exploit temporal attention mechanism to exploit temporal structure for video captioning. Yu *et al.* [12] proposed an approach which used hierarchical RNN to capture temporal information for video captioning. In addition, Yang *et al.* [21] adopted a standard generative adversarial network (GAN) architecture for video captioning, which aims at compensating for the deficiencies of LSTM-based video captioning methods that generally show potential to effectively handle temporal nature of video data.

Temporal Attention Mechanism: The early work on encoder-decoder framework [20] tried to represent the information using a single, temporarily folded feature vector, which is likely to lead to confusion, because different events and objects in temporal sequence may fuse incoherently [11]. Therefore, a captioning model should be clever enough to exploit the temporal structure underlying the video sufficiently.

Thus, temporal attention mechanism (TAT) has been proposed recently. It can make the decoder generate each word according to semantically most relevant temporal segments. Compared to the previous encoder-decoder framework, the temporal attention-based encoder-decoder framework can dynamically decode a subset of video frames for word prediction. Thus, it can exploit temporal structure underlying video clips sufficiently, e.g., it is possible to tell the order of the appearance of two objects from the temporal segments, but also aligns encoded video frames with target words precisely.

Exploitation of Local Features: The use of global features that extract information from each frame to the most prominent objects is an effective solution that was widely used in previous work [22]–[27]. Unfortunately, this has one potential drawback of losing information which could be useful for richer, more descriptive descriptions [28]. As we know, a video contains more kinds of features than an image, such as global and motion features at frame-level, as well as local features at object-level *et al.* [29]. Since the global features and motion features are extracted at a coarse frame level, they represent rough semantic concepts of corresponding video frames and they may result in incorrect recognition error. Hence, introducing local features to represent accurate semantic concepts of objects is important for describing the content of a video. A little existing work in video captioning tried to use local features. Shetty *et al.* [30] utilized pre-trained SVM classifier to extract local features and integrates them with

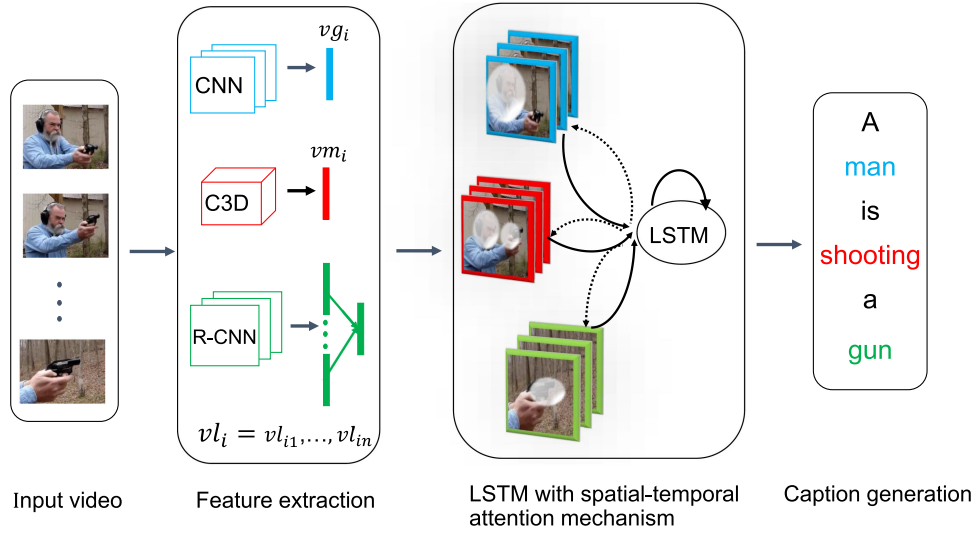

Fig. 2. Illustration of our proposed STAT video caption framework based on spatial-temporal attention mechanism.

global features. Nevertheless, they merely use simple averaging strategies to handle these local features. Yu *et al.* [12] considered exploiting local features at object-level instead of global features. They first use Optical Flow to roughly detect a bounding box for the actor on each frame, and then extract K image patches of size 220×220 along the lower part of the box border. Thus, these local features are actually a certain part of the actor. Finally, they use local features alone and pool them together to a single vector on each frame. They argue that when calculating the attention weights of these frames, this routine will result in both temporal and spatial attention mechanism in the sentence generator.

III. EXPLOITING SPATIAL-TEMPORAL STRUCTURE IN VIDEO CAPTIONING

In this part, we deeply study the main contributions of this paper and put forward an approach of using the spatial and temporal structure for video captioning.

A. Overall Framework

To begin with, we describe our overall framework, based on the popular ConvNet + LSTM architecture [31]–[37]. It mainly consists of three important processes as shown in Fig. 2.

First of all, we use 2-D/3-D Convolutional Neural Network (CNN) and Region-based Convolutional Neural Networks (R-CNNs) to encode the video inputs to a set of fixed length vector representation. Deep convolutional neural networks (CNNs) and regions with convolutional neural networks (R-CNNs) have been found to be useful in computer vision tasks such as object localization and detection. For example, 2-D CNN such as GoogleNet can represent an image as a single feature vector. 3-D CNN such as C3D can represent consecutive frames as a single feature vector. R-CNN such as Faster R-CNN can represent a region or object as a single feature vector. The feature vector is from upper or intermediate layers of a CNNs as a high-level feature for vision [11]. Most of state-of-the-art work

therefore exploits a pre-trained 2-D/3D CNNs and R-CNNs as an encoder. We will follow the implementation of these work to exploit CNNs and R-CNNs as the encoder.

Secondly, we fuse three kinds of features via two-stage attention mechanism. In this phase, when the current semantic context is given, spatial attention mechanism firstly makes the decoder to select local features with more spatial attention weights, which represent the significant regions. Then, temporal attention mechanism make the decoder to select global and motion features, as well as local features representing significant regions. Finally, three types of features are fused to represent the information of key frames.

In the end, we use the language model to generate sentences with dynamic temporal features. In this paper, LSTM is used as a language model, because it can effectively capture long-term sequence information.

B. Encoder: Convolutional Neural Network

The encoder network is designed for learning a proper representation of visual information. Then the decoder network can form corresponding sentences according to the output of the encoder. In the encoder network, we extract global feature and local feature from every frame, and extract the motion feature from video clips. Hence, a video inputted to encoder network will finally be transformed into a sequence of visual information: $V = \{v_1, \dots, v_k\}$, where each $v_i = \{vg_i, vl_i, vm_i\}$, and k refers to number of frames. The vg_i extracted from 2-D CNN represents one of the global features which contain the context information of a video frame. The vm_i extracted via 3-D CNN represents one of the motion features which characterize punctuated actions. The vl_i extracted via R-CNN represents one of the local features of maintaining more accurate object information.

C. Spatial-Temporal Attention Mechanism

As far as primates and human beings are concerned, visual attention mechanism is a significant mechanism. Thus, we exploit

visual attention mechanism of human beings to design a spatial-temporal attention mechanism (STAT) method. When human beings are asked to describe a certain content of video, they do not describe everything in a video. Instead, they tend to talk more about semantically more important spatial-temporal segments in the video. Thus, we argue that before generating each target word, the decoder firstly should exploit spatial structure to catch semantically most relevant objects on each frame. Then, it should exploit temporal structure to track their trajectories and studies the interactions among them on consecutive frames. We will elaborate the details of proposed two-stage attention mechanism in Section D and Section E.

D. Exploiting Spatial Structure: A Spatial Attention Mechanism

Since a video has multiple objects, the decoder should selectively focus on the most significant regions of a video sequence. We use spatial attention mechanism to dynamic weighted sum of the top- n local features, i.e., $vl_i = \{vl_{i1}, \dots, vl_{in}\}$, to obtain a single spatial local feature $\Psi_i(VL)$ on each frame such that

$$\Psi_i^{(t)}(VL) = \sum_{j=1}^n \alpha_{ij}^{(t)} vl_{ij}, \quad (1)$$

where $\alpha_{ij}^{(t)}$ represents spatial attention weights. It is calculated at each time and $\sum_{j=1}^n \alpha_{ij}^{(t)} = 1$. When the previous words are given, i.e., y_1, \dots, y_{t-1} , unnormalized relevance scores $e_{ij}^{(t)}$ will be measured by spatial attention functions:

$$e_{ij}^{(t)} = w_l^T \tanh(W_e h_{t-1} + U_e vl_{ij} + z_e), \quad (2)$$

where w_l^T , W_e , U_e , z_e are the shared parameters to be learned by our model at all the time steps.

The unnormalized relevance scores, which can reflect the relevance of the j -th local features in the input video. will be normalized over n local features to calculate attention weights $\alpha_{ij}^{(t)}$:

$$\alpha_{ij}^{(t)} = \exp\{e_{ij}^{(t)}\} / \sum_{j'=1}^n \exp\{e_{ij'}^{(t)}\}. \quad (3)$$

The spatial attention mechanism makes the decoder to selectively catch the most significant regions according to increasing the attention weights.

E. Exploiting Temporal Structure: A Temporal Attention Mechanism

With regards to a generated sentence, each word should be in line with different temporal segment of the video. Hence, while generating each sentence, the model should attend to different temporal segments at each time. For this reason, we respectively exploit temporal attention mechanism to dynamically weighted sum of the global, local and motion features such that

$$\varphi_t(VG) = \sum_{i=1}^k \beta_i^{(t)} vg_i; \quad (4)$$

$$\varphi_t(VM) = \sum_{i=1}^k \delta_i^{(t)} vm_i; \quad (5)$$

$$\varphi_t[\Psi(VL)] = \sum_{i=1}^k \gamma_i^{(t)} \Psi_i(VL), \quad (6)$$

where $\sum_{i=1}^k \beta_i^{(t)}$, $\sum_{i=1}^k \delta_i^{(t)}$ and $\sum_{i=1}^k \gamma_i^{(t)}$ are all equal to 1. $\beta_i^{(t)}$, $\delta_i^{(t)}$ and $\gamma_i^{(t)}$ are calculated respectively at each time step t inside the LSTM decoder. We denote by them as the temporal attention weights at time t .

The relevance scores, namely $b_i^{(t)}$, $c_i^{(t)}$ and $d_i^{(t)}$, will be measured by three temporal attention functions:

$$b_i^{(t)} = w_k^T \tanh(W_b h_{t-1} + U_b vg_i + z_b); \quad (7)$$

$$c_i^{(t)} = w_e^T \tanh(W_c h_{t-1} + U_c vm_i + z_c); \quad (8)$$

$$d_i^{(t)} = w_r^T \tanh(W_d h_{t-1} + U_d \Psi_i(VL) + z_d), \quad (9)$$

where w_*^T , U_* and z_* are shared by all the features respectively.

After that, the relevance scores will be normalized via *softmax* function:

$$\beta_i^{(t)} = \exp\{b_i^{(t)}\} / \sum_{i'=1}^k \exp\{b_{i'}^{(t)}\}; \quad (10)$$

$$\delta_i^{(t)} = \exp\{c_i^{(t)}\} / \sum_{i'=1}^k \exp\{c_{i'}^{(t)}\}; \quad (11)$$

$$\gamma_i^{(t)} = \exp\{d_i^{(t)}\} / \sum_{i'=1}^k \exp\{d_{i'}^{(t)}\}. \quad (12)$$

When obtaining three kinds of temporal features, they are fused by sum fusion such that

$$\varphi_t(V) = \varphi_t(VG) + \varphi_t(VM) + \varphi_t[\Psi(VL)]. \quad (13)$$

Finally, each $\varphi_t(V)$ will input to LSTM unit at each time step. The temporal attention mechanism makes the decoder to selectively focus on a subset of frames according to increasing the attention weights of the corresponding three different kinds of features. In this way, the decoder can utilize the temporal structure sufficiently. Consequently, these two attention mechanisms are systematically integrated into the encoder-decoder neural framework, which can focus on how to predict significant regions more precisely while focusing on more semantically relevant video frames.

F. Decoder: Long Short-Term Memory Network

The decoder network can convert visual features into a word sequence $Y = \{y_1, y_2, \dots, y_m\}$, which summarizes the video contents. Hence, each $\varphi_t(V)$ will be fed into LSTM unit at each time step, which is formulated as follows:

$$i_t = \sigma(W_i E[y_{t-1}] + U_i h_{t-1} + A_i \varphi_t(V) + b_i); \quad (14)$$

$$f_t = \sigma(W_f E[y_{t-1}] + U_f h_{t-1} + A_f \varphi_t(V) + b_f); \quad (15)$$

$$o_t = \sigma(W_o E[y_{t-1}] + U_o h_{t-1} + A_o \varphi_t(V) + b_o); \quad (16)$$

$$g_t = \sigma(W_g E[y_{t-1}] + U_g h_{t-1} + A_g \varphi_t(V) + b_g); \quad (17)$$

$$c_t = c_{t-1} \odot f_t + i_t \odot g_t; \quad (18)$$

$$h_t = o_t \odot \phi(c_t), \quad (19)$$

where $\varphi_t(V)$ is the encoder temporal representation. E is a word embedding matrix, and we refer to $E[y_{t-1}]$ as an embedding vector of word y_{t-1} . σ is a *sigmoid* activation function; ϕ is a *tanh* function, y_{t-1} is the previous word; h_{t-1} is the previous hidden state; Besides, W_* , U_* , A_* and b_* are the shared weight matrices and bias to be learned. Finally, the probability distribution of a series of target words at each time will be obtained via a single hidden layer:

$$\hat{y}_t = \text{softmax}(U_y \phi(W_y [h_t, \varphi_t(V), E[y_{t-1}]])) + b_y, \quad (20)$$

where $[h_t, \varphi_t(V), E[y_{t-1}]$ denotes the concatenation of the three vectors. W_y , U_y , and b_y are the shared weight matrices and bias to be learned. The *softmax* function allows us to interpret \hat{y}_t as the probabilities of the distribution $p(y_t | y_{<t}, V, \theta)$ over words. Decoder can approximately find the sentence with the highest probability by using the beam search.

IV. EXPERIMENT

A. Dataset and Evaluation Metrics

Dataset: The extensive experiments are conducted on two famous video captioning benchmarks: MSVD [38] and MSR-VTT-10K [39]. The MSVD has 1970 video clips including a series of human annotated language sentences. There are 80,839 sentences in total, with about 41 annotated sentences per clip. The words in all the sentences form a vocabulary that contains 13,010 unique words. Following [11], the dataset can be divided into a training set of 1,200 video clips, a validation set of 100 clips, and a test set consisting of the rest of 670 clips. The MSR-VTT-10K [39] consists of 10,000 video clips that is the most challenging dataset for video captioning so far. We use the official split with 6513 videos for training, 497 for validation and 2990 for testing.

Evaluation Metrics: There are kinds of approaches with regards to the evaluation of generated sentences have been adopted, such as BLEU [40], METEOR [41] and CIDEr [42]. BLEU has been widely used to evaluate the performance of machine translation. It is mainly based on the n-gram accuracy. The METEOR is proposed to correct a kind of problems in BLEU. It can generate an alignment according to exact token matching to judge the word correlation between candidate and reference sentences. CIDEr exploits human consensus to evaluate video descriptions. We get all the results in this paper according to the Microsoft COCO evaluation server [43].

B. Feature Extraction

Global Feature Extraction: For frame-level global features, on MSVD, we adopt 1024-dimension *pool5*/7 \times 7_s1 layer from GoogLeNet [44] and denote them as $VG = \{vg_1, \dots, vg_k\}$. On MSR-VTT-10K, we have tried to use two CNN features for frame-level global features, such as GoogleNet *pool5*/7 \times 7_s1 and ResNet-152 [45] *pool5*. Finally we find that ResNet-152 *pool5* gets best performance on this

task. Therefore, we use *pool5* feature from ResNet-152 as global feature on MSR-VTT-10K.

Motion Feature Extraction: For motion features, we use the 4096-dimensional fc6 layer from C3D [46] pre-trained on the Sports-1M video dataset [47]. We take continuous 16 frames as the input short clips for the C3D, similar as the default setting. The C3D features are denoted as $VM = \{vm_1, \dots, vm_k\}$.

Object Detection: During the training and testing phase, detecting kinds of local features vl_i is an indispensable part of our STAT. In the recent years, the most advanced approaches in general class of detection objects are mainly grounded on CNN. Girshick *et al.* [48] proposed a multilevel network called Regions with Convolutional Neural Networks (R-CNN). It aims to train depth CNN for classifying proposals of target detection. In order to accelerate the training speed, Fast R-CNN and Faster R-CNN are proposed constantly. In this paper, we exploit Faster R-CNN [49] as our object detector due to its accuracy in much object detection work.

Pre-trained Faster R-CNN model is used to directly detect kinds of objects in video frames. Faster R-CNN model will obtain a series of rectangular object proposals, each with a class confidence score, via taking an image (of any size) as input. The higher the score, the more likely there is an object for a certain class. For the purpose of alleviating redundant computation complexity, we attempt to make a set of strategies to tackle it. Firstly, the number of proposals are reduced from 300 (e.g. default setting) to 100. The reason is that when we use the top-ranked 100 proposals at a testing phase, it also achieves a better performance [49]. In fact, Non-Maximum Suppress algorithm (NMS) will further reduce the average number of proposals. Furthermore, we only detect objects in 28 equally-spaced frames in each video in that there is little change in adjacent frames. Finally, we trained Faster R-CNN model detecting 80 objects on MS COCO dataset.

Local Feature Extraction: After that, we chose the top- n objects that represent important local objects via their class confidence scores $\{s_1, s_2, \dots, s_n\}$. In this work, we attempt to use two kinds of local features, i.e., visual features and label features. We will elaborate how to extract them as follows:

- 1) *Visual Feature Extraction:* For local visual features, we represent top- n objects as 4096-dimensional features respectively, which are extracted from the fc7 layer in the Faster R-CNN network. After that, we obtain a series of local visual features $vl_i = \{vl_{i1}, \dots, vl_{in}\}$ where $vl_{ij} \in \mathbb{R}^{4096}$ in each frame;
- 2) *Label Feature Extraction:* For local label features, we firstly obtain names of top- n objects. To make these important objects relate to semantic space, we connect them to semantic relationship using Glove [50], which maps each object name to 300 dimension semantic space. The embedded label features then are used to form our visual-semantic attention context. Finally, we obtain a set of local label features $vl_i = \{vl_{i1}, \dots, vl_{in}\}$ where $vl_{ij} \in \mathbb{R}^{300}$ on each frame.

Finally, we select 28 equally-spaced frame global features, local features and clip motion features as visual inputs.

Fig. 3. Illustration of the performance with different top-n objects which are represented by local visual features on MSVD.

C. Model and Training

Our video captioning framework is shown in Fig. 2. On MSVD, the decoder network has one LSTM layer with 1024 cells. Each word is embedded to a 512-dimensional vector when it is fed to the LSTM layer. Especially, on MSR-VTT-10K, in order to alleviate computation and keep consistent with the [51]–[54], the hidden layer size and word embedding size are all set to 512. On two both datasets, learning rate is set to 2×10^{-4} empirically.

In training phase, firstly, we define the objective function of generating words as negative logarithm of the likelihood. Secondly, we use the Adadelta algorithm [55] with the gradient computed by the back propagation algorithm. Finally, we minimize the objective function over all the training set:

$$L(\theta) = -\frac{1}{N} \sum_{n=1}^N \sum_{i=1}^{t_m} \log p(y_i^m | y_{<i}^m, x^m, \theta), \quad (21)$$

where there are N training video-description pairs (x^m, y^m) . θ are parameters of the video captioning model and each description y^m is t_m words long.

In testing phase, we use beam search with size 5 during sentence generation. We conduct our experiments via Theano Framework.

D. Video Captioning Experiments and Results

in this section, we will conduct five comparative experiments as follows:

- Exploring the proper number of top-n objects when exploiting local visual and label features, respectively;
- Comparison of different local features ;
- Comparison of different kinds of features ;
- Comparing four method to process local features, i.e., 1) no exploiting; 2) mean pooling; 3) max pooling; 4) spatial attention mechanism;
- Comparing STAT with state-of-the-art method.

Evaluation on Different Number of Local Features: How many local features to select is critical to generate the correct description. For the purpose of obtaining an appropriate number of local features, in this section, we respectively use local visual and label features to conduct experiments. Then, we analyze the influence of different number of them for video captioning. Here, we chose 4, 6, 8, 10 and 12 objects in each frame to conduct experiments.

1) *The Determination of The Number of Local Visual Features:* Figs. 3 and 4 respectively show the results on each benchmark with different top-n objects. These objects are represented by local visual features. Each subfigure shows the accuracy of different n with the same metric and each color shows the accuracy of the same n with different metrics. From these experiments, we find that it realizes best performance when choosing top-10 objects in each frame on MSVD. For MSR-VTT-10K, we find that it achieves better performance when choosing top-6 objects. Hence, we finally choose that n is equal to 10 on MSVD and 6 on MSR-VTT-10K to carry out our following experiments.

2) *The Determination of The Number of Local Label Features:* Figs. 5 and 6 respectively show the results on each benchmark with different top-n objects. These objects are represented by local label features. Each subfigure shows the accuracy of different n with the same metric and each color shows the accuracy of the same n with different metrics.

For MSVD, we observe that it achieves better performance when choosing 6 local features. For MSR-VTT-10K, we find using 8 local features has better performance. Therefore, we argue that 6 and 8 are the proper number for each benchmark, respectively. Hence, we finally choose that n is equal to 6 on MSVD and 8 on MSR-VTT-10K to carry out our following experiments.

According to these experiments, we obtain a finding that the number of either local visual or local label features should be moderation rather than the bigger the better. If the number of local features is larger, there may have some non-object information to impact the correction of prediction. In contrast, if the number of local features is smaller, there may miss some critical object information, which could lead to generate incomplete description.

Comparison of Different Local Features: In the task of video description, we not only pursue to more relevant description sentences, but need to consider the computation complexity and data amount. Therefore, we first compare the best performance of different local features selected from the results in above experiments. Then, we give an overall consideration that selecting which kind of local features would be better. The comparison results are shown in the Table I and Table II.

Table I shows the comparison results of the exploitation of different local features on MSVD. Compared with exploiting local label features, the performance of exploiting local visual features is better on BLEU-4 and CIDEr. By contrast, as shown in Table II, compared with exploiting local label features, the

Fig. 6. Illustration of the performance with different top-n objects which are represented by local label features on MSR-VTT-10K.

TABLE I
COMPARISON EXPERIMENTS FOR DIFFERENT LOCAL FEATURES ON MSVD

Method	Attention	Feature Types			Local Number	Evaluation Metric		
		Global	Motion	Local		BLEU4	METEOR	CIDEr
STAT	Spatial & Temporal	GoogleNet	C3D	RCNN-fc7	10	0.520	0.333	0.738
STAT	Spatial & Temporal	GoogleNet	C3D	Glove	6	0.514 (-1.2% ↑)	0.335 (0.6% ↑)	0.724 (-0.2% ↑)

performance of exploiting local visual features on MSR-VTT-10K becomes badly on BLEU-4 and METEOR, and their scores in CIDEr has little difference.

Meanwhile, compared to using local visual features, we note that when using local label features, the performance over all metrics on MSVD averagely decreases 0.27%, but averagely increases 1.53% over all metrics on MSR-VTT-10K. Especially, local label features with dimension of 300 are much smaller than local visual features with dimension of 4096, so they take up much less space and are loaded faster. Hence, from the perspectives of performance and practical operation, we finally argue that using local label features is a better selection.

Comparison of Different Kinds of Features: In the task of video description, global, motion and local features are useful for generating accurate descriptions. Hence, in this section, we carry out four experiments to verify the effectiveness of three kinds of features, namely global, motion and local features, and fusion form of these three kinds of features for describing videos. The specific configurations of the four experiments are shown as follows:

- 1) GloFeat: Only employing the global features which are extracted from GoogleNet.
- 2) MotFeat: Only employing the motion features which are extracted from C3D.

*V represents local visual features. *L represents local label features.

- 3) Loc_V: Only employing the local visual features which are extracted from fc7 layer in Faster-RCNN.
- 4) Loc_L: Only employing the local label features which are extracted from Glove model.
- 5) STAT_V: Employing the global, motion and local visual features.
- 6) STAT_L: Employing the global, motion and local label features.

The comparison results are shown in the Table III and Table IV. On both benchmarks, firstly, according to results of the three kinds of single feature experiments, we found that the effectiveness of only using global features or motion features is better than only using local features. The reason may be that global features represent overall semantic concepts of corresponding video frames, and motion features characterize punctuated actions such as “jumping up” or “standing up”. These two kinds of features can both roughly summarize the content of a video. Especially, global features can provide the relationship of several objects that is useful for generating video descriptions. However, only using local features cannot

summarize the content of a video. By comparing STAT experiment with the others, we observe that fusion form can get the best performance. Our conjecture is that STAT can not only get overall global context information, but capture local object information and their relationship.

Evaluation on Exploitation of Local Features: Local features are very critical for obtaining specific information in object detection. Compared to a single image, a video is composed of multiple frames, so it naturally has more objects. Hence, we conduct four experiments to explore the effectiveness of local features and how to properly process them. The specific configurations of the four experiments are shown as follows:

- 1) TAT-NL: Only employing the global features and motion features with temporal attention.
- 2) TAT-L_{mean}: First, employing mean pooling method to process top-*n* local features and get a single local representation on each frame. Then, employing temporal attention mechanism to respectively select most relevant global, local and motion features and fusing them by sum fusion.
- 3) TAT-L_{max}: First, employing max pooling method to process top-*n* local features and get a single local representation on each frame. Then, employing temporal attention mechanism to respectively select most relevant global, local and motion features and fusing them by sum fusion.
- 4) STAT: First, employing spatial attention mechanism to dynamically assign attention weights for each local features to select significant regions with maximal attention weights. Then, employing temporal attention mechanism to selectively attend to important temporal segments with maximal attention weights. Finally, these selected features are fused by sum fusion.

Table V and Table VI show the results of these experiments. On both benchmarks, firstly, according to results of the TAT-NL experiment with TAT-L_{mean} experiment, we observe that former gets a better performance. Our conjecture is that mean pooling fuses all the objects into a single vector representation, leading to the loss of spatial structure underlying the input frame. Hence, these local features might become noises to disturb other features.

Secondly, from the comparison result of the TAT-NL experiment with TAT-L_{max} experiment, we observe that using local features by max pooling will achieve better performance. We argue that compared to mean pooling, max pooling not only selects the most prominent object, but also don't impact on the spatial structure underlying the input frame. Hence, when introducing these local features, if we don't confuse them and keep spatial structure of input frame, these local features indeed improve the performance.

TABLE V
COMPARISON EXPERIMENTS FOR EXPLOITATION OF LOCAL FEATURES ON MSVD

Method	Attention	Feature Types			Local Number	Evaluation Metric		
		Global	Motion	Local		BLEU-4	METEOR	CIDEr
TAT-NL	Temporal	GoogleNet	C3D	-	0	0.464	0.318	0.625
TAT- L_{mean}	Temporal	GoogleNet	C3D	R-CNN fc7	10	0.435	0.307	0.597
TAT- L_{max}	Temporal	GoogleNet	C3D	R-CNN fc7	10	0.448	0.326	0.669
STAT	Spatial & Temporal	GoogleNet	C3D	R-CNN fc7	10	0.520	0.333	0.738

TABLE VI
COMPARISON EXPERIMENTS FOR EXPLOITATION OF LOCAL FEATURES ON MSR-VTT-10K

Method	Attention	Feature Types			Local Number	Evaluation Metric		
		Global	Motion	Local		BLEU-4	METEOR	CIDEr
TAT-NL	Temporal	ResNet-152	C3D	-	0	0.371	0.264	0.398
TAT- L_{mean}	Temporal	ResNet-152	C3D	Glove	8	0.343	0.243	0.319
TAT- L_{max}	Temporal	ResNet-152	C3D	Glove	8	0.374	0.256	0.406
STAT	Spatial & Temporal	ResNet-152	C3D	Glove	8	0.393	0.271	0.438

Finally, by comparing STAT with the TAT- L_{max} , we find STAT has better performance on all evaluation metrics. Our conjecture is that the only one most prominent object is insufficient for video description task. As shown in the 5th of Fig. 7, if only ‘person’ has the most high class confidence score, other objects, such as ‘bottle’, ‘bowl’ *et al.*, will be overlooked in max pooling.

According to above all analyses, we argue that it is indispensable to incorporate spatial attention mechanism into encoder-decoder network. We draw a conclusion that temporal and spatial cues are complementary. When both attention mechanisms are utilized simultaneously, it will achieve the best performance

Comparison with State-of-the-art Methods: Finally, we compare our STAT method with several state-of-the-art methods. On MSVD, here, we choose local visual features and compare STAT with five methods: HRNE [10], TA [11], h-RNN [12], LSTM-E [36], and M-Fusion [9]. HRNE exploited a hierarchical recurrent encoder to model video temporal information. TA is the first work to utilize temporal attention mechanism for video captioning. h-RNN proposed an approach which use hierarchical RNN to handle the problems in video captioning. LSTM-E intended to explore visual semantic embedding and learning of LSTM. M-Fusion explores a proper method to fuse different types of features with attention model. On MSR-VTT-10K, we choose local label features and compare STAT with the top-5 results from the 1st MSR-VTT challenge on the LeaderBoard,¹ including v2t_navigator [52], Aalto [51], VideoLAB [53], ruc-uva [54] and Fudan-ILC,² which are all based on multiple types of features. For instance, v2t_navigator and VideoLAB exploit almost all the features extracted from this dataset, such as global, motion, aural and category features. ruc-uva and Aalto exploit global, motion and category features.

²They didn’t submit the report for this challenge.

1) Results on MSVD: We show the results on MSVD in Table VII. Our STAT realize the best performance on BLEU-4 and CIDEr compared with other work. The main feature of BLEU is for corpus-level comparisons where many n-gram matches exist [43]. CIDEr, a consensus-based metric, is used to reward a description which conforms to the writing habits of human beings. Our STAT therefore not only generate accurate sentences but maintain human language habits. We note HRNE has better performance than us on METEOR. We compute the relevant improvements based on them. Compared to them, in terms of METEOR, our STAT decreases 1.8%. In terms of BLEU-4, however, our STAT increases 11.3%. Hence, our STAT can generate more relevant description sentences than them.

2) Results on MSR-VTT-10K: We report the results on MSR-VTT-10K in Table VIII. By comparing our STAT with the top-5 results from 1st MSR-VTT-10K challenge, which represent the state-of-the-art results on this benchmarks, we note that our STAT method obtains a medium level on all evaluation metric. Compared the existing methods on this benchmark, STAT hardly have any improvements. There may be several likely reasons accounting for this limited improvements. Firstly, the human annotated sentences of the same video are more diverse on this challenging dataset. Secondly, considering the fact that 836 out of 23,667 words in MSR-VTT-10K annotated sentences are misspelled (e.g., ‘basketball’ and ‘peson’) [29], If the spelling is not corrected, it is much more difficult to describing the content of a video on this dataset. In addition, the dataset is more challenging due to the diversity of its videos. This might result in misprediction when detecting objects on this dataset, so weakening the effectiveness of local features and the advantage of spatial attention mechanism. Therefore, the detection of tiny object is worth exploring. We will attempt to train an object detector based on videos to improve the accuracy of our STAT in the future. Finally, v2t_navigator [52], Aalto [51], VideoLAB [53], and ruc-uva [54] all use category features and demonstrate that its useful to improve the performance. MSR-VTT-10K has been

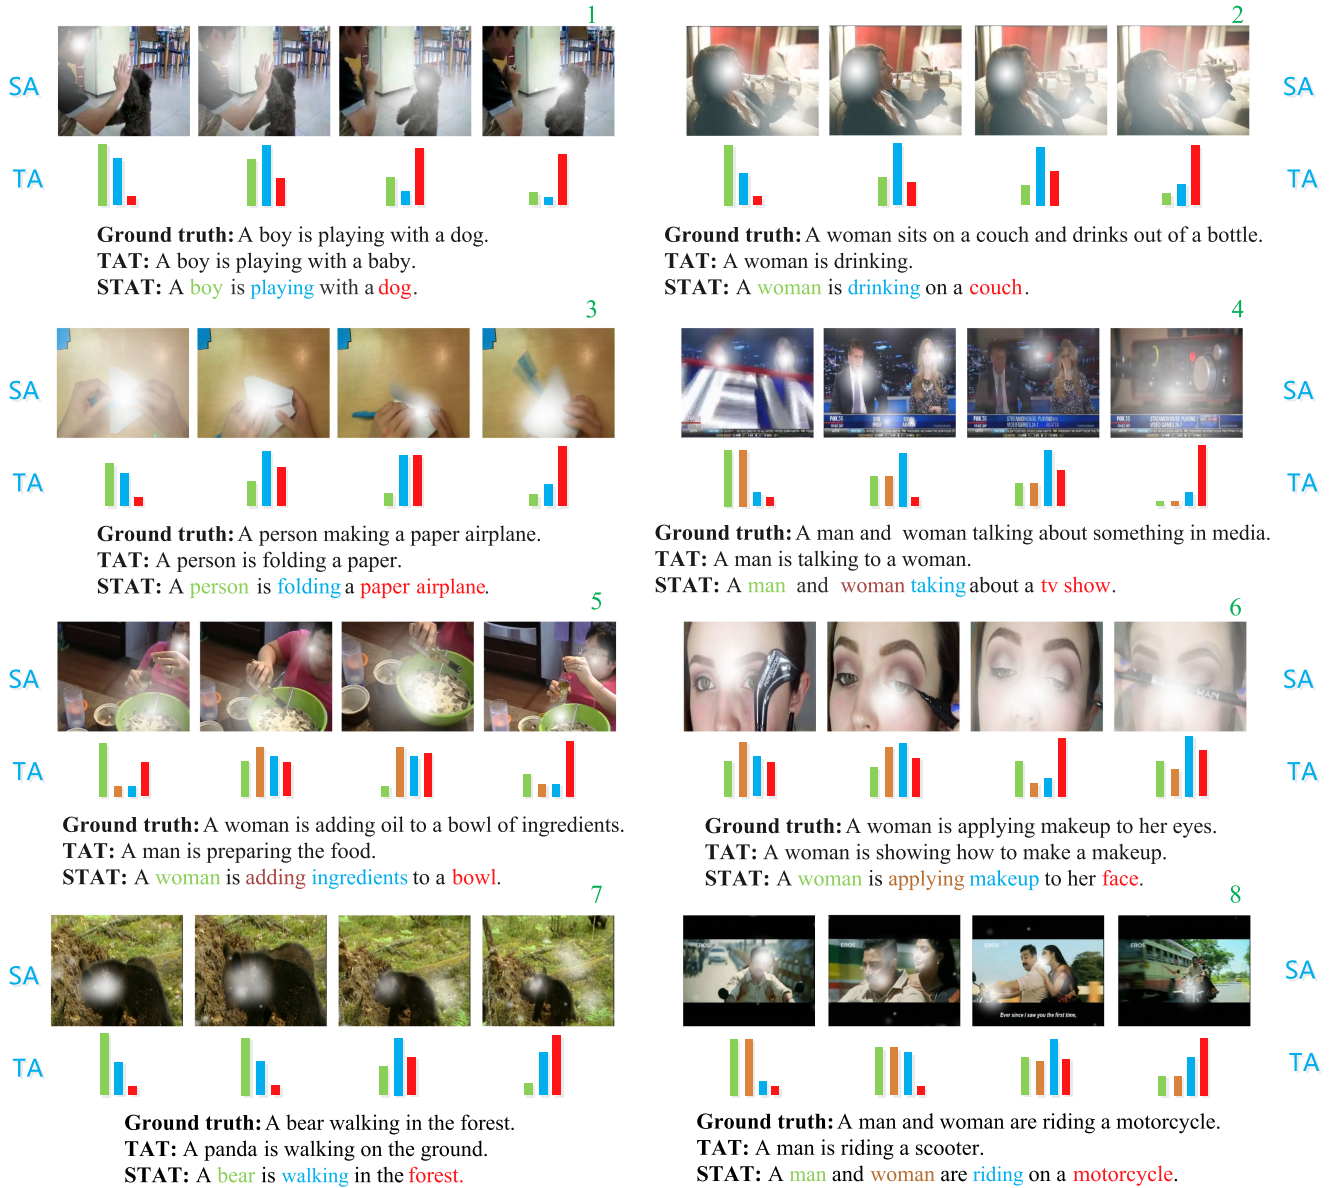

Fig. 7. Eight representative samples from MSVD and MSR-VTT-10K, which also involve the sentences from ground truth, temporal attention mechanism (TAT) and spatial-temporal attention mechanism (STAT). In the figure, SA and TA indicate the results of spatial and temporal attention. The white aperture in each frame indicates the change in the degree of significance of corresponding regions in the spatial attention stage. The bar plot under each frame are the temporal attention weights for this frame when the corresponding word (color-coded) was generated in the stage of temporal attention.

classified as total 20 different categories (e.g., music, tv shows, sports, etc.) by the official. Each video is tagged with a category. Category features provide a strong prior information about video content. It is also useful for dynamically weighting other kinds of features [52]. Besides, most of them use the aural features. Aural features are complementary to visual features, which are especially useful to distinguish different scene events. However, our goal in this work is to improve the visual encoder, which is quite different from their research.

E. Qualitative Analysis

Although we can evaluate our model through the evaluation mechanism described in [43], the scores do not directly reflect the performance of the generated sentences by STAT.

Therefore, we visualized the spatial and temporal attention results of some representative videos from MSVD and MSR-VTT-10K, as shown in Fig. 7. In the figure, SA and TA respectively represent the spatial and the temporal attention result. Fig. 7 includes the sentences obtained from TAT, our STAT and ground truth.

In Fig. 7, we can clearly see that compared to TAT using temporal attention, since we integrate the spatial attention with temporal attention during the description generation, the sentences generated by STAT can contain more details (eg ‘paper airplane’, ‘tv show’, ‘bowl’) and less error. Besides, STAT could not only select key frames which relate to each word, but could catch significant regions in these frames. For instance, in the *No.1* video, while generating the word ‘boy’, first frame is selected via temporal attention mechanism. Then, the discriminative face

ruc-uva [55]	0.387	0.269	0.459
Fudan-ILC	0.387	0.268	0.419

*L represents local label features.

area of the boy is caught via the spatial attention mechanism. And then, when the word of ‘dog’ is generated, STAT turns to select third and fourth frames according to previous generated words. However, in the sentence generated by TAT, the ‘dog’ is misrecognized as the ‘baby’. In another example, TAT is hard to determine the place where ‘a man and woman talking’ in *No.4* video. By comparison, STAT recognizes the ‘couch’ accurately, and successfully identifies the ‘dog’ and other details, because we augment the local features, and STAT can selectively catch significant regions. Above representative examples further demonstrate that it is indispensable to integrate spatial attention mechanism with temporal attention mechanism in the task of video captioning.

V. CONCLUSION

Existing methods based on temporal attention mechanism cannot catch significant regions in frames, so they might suffer from the problems of recognition error and detail missing. In this paper, we propose a spatial-temporal attentional mechanism. Different from previous methods, we take into account both the spatial and temporal structures in a video, so it learns the ability to not only focus on a subset of frames, but further catch significant regions in that subset. Extensive experiments conducted on two well-known benchmarks show that our STAT achieves state-of-the-art performance on both evaluation benchmarks. We prove this by quantitatively analyzing the spatial and temporal attention weights in the process of sentence generation. Consequently, our method can generate detailed and accurate descriptions. In the future, we will attempt how to model the relationship among local features to improve the effectiveness of them.

Since both spatial and temporal information in a video are critical to understand contents of it, any encoder-decoder based on video understanding task can added our spatial-temporal attention method to promote the overall performance.

ACKNOWLEDGMENT

Chenggang Yan received the B.S. degree in control science and engineering from Shandong University, Shandong, China, in 2008, and the Ph.D. degree in computer science from Chinese Academy of Sciences University, Beijing, China, in 2013. He is currently a Professor with the Department of Automation, Hangzhou Dianzi University. His research interests include computational photography and pattern recognition and intelligent system.

Yunbin Tu received the B.S. degree in automation from Hangzhou Dianzi University, Hangzhou, China, in 2018. His research interests include deep learning and video captioning.

Xingzheng Wang received the Ph.D. degree in computer science from Hong Kong Polytechnic University, Hong Kong, in 2013. He has been a Post-doctoral Fellow and Assistant Professor with the Graduate School, Shenzhen of Tsinghua University, Shenzhen, China, since July 2013. He is currently an Associate Professor with the College of Mechatronics and Control Engineering, Shenzhen University, Shenzhen, China. His research interests include computational imaging, computer vision, and pattern recognition.

Yongbing Zhang received the B.A. degree in english and the M.S. and Ph.D. degrees in computer science from the Harbin Institute of Technology, Harbin, China, in 2004, 2006, and 2010, respectively. He joined Graduate School, Shenzhen, Tsinghua University, Shenzhen, China, in 2010, where he is currently an Associate Professor. He was the receipt of the Best Student Paper Award at IEEE International Conference on Visual Communication and Image Processing in 2015 and the Best Paper Award at the 19th Pacific-Rim Conference on Multimedia (PCM 2018).

His current research interests include signal processing, image/video coding, and machine learning.

Yongdong Zhang received the Ph.D. degree in signal and information processing from Tianjin University, Tianjin, China, 2002. He is currently a Professor with the School of Information Science and Technology, University of Science and Technology of China, Anhui. His research interests include multimedia content analysis, cyberspace Security, and computational imaging.

Xinhong Hao received the B.S., M.S., and Ph.D. degrees in technical and electrical engineering from Beijing Institute of Technology University, Beijing, China, in 1996, 1999, and 2007, respectively. She is currently an Associate Professor with the Department of Technical and Electrical, Beijing Institute of Technology University. Her research interests include intelligent detection and control, radio target detection and signal processing, and information perception and confrontation.

Qionghai Dai received the M.S. and Ph.D. degrees in computer science and automation from Northeastern University, Shenyang, China, in 1994 and 1996, respectively. He is currently a Professor with the Department of Automation and the Director of the Broadband Networks and Digital Media Laboratory, Tsinghua University, Beijing, China. He has authored or coauthored more than 200 conference and journal papers and two books. His research interests include computational photography and microscopy, computer vision and graphics, intelligent signal processing. He is an Associate Editor of the Journal of Visual Communication and Image Representation, the IEEE TRANSACTIONS ON NEURAL NETWORKS AND LEARNING SYSTEMS, and the IEEE TRANSACTIONS ON IMAGE PROCESSING.
